

Predicted acidic surface profile of PL25_M23 compared with reference cell-wall hydrolases

Cautious interpretation: panels show a PREDICTED acidic-surface profile for PL25_M23 (pI 4.54; net charge −22.4; charge density −6.9 %) relative to four reference cell-wall hydrolases. This is consistent with — but does NOT prove — halophile-type adaptation. Confirmation requires direct biochemical tests of activity / stability under high-salt conditions. Surfaces are coloured by per-atom side-chain charge using a single rule applied identically to all five proteins; absolute vacuum-electrostatic-potential values were not used as the comparison metric because their numeric scale is protein-specific. Bar-chart values from Biopython ProteinAnalysis (Henderson–Hasselbalch, pH 7.0).
